## HawkesModel

### Fitting Hawkes model to marathon record data

Produce estimates for model, exponential Hawkes process, using MLE: - baseline intensity, - reproduction mean

- exponential fertility function rate

Note: data is in days from the first world record which is set as time 0. The model is fit through day 40,300 (the last record is at day 40,231).

Three parameter estimates are first output.

NOTE: the results change if one doesn't set a seed...and by more than I would expect!!!! Maybe need to set starting values or something to ensure optimal?

```
record_table_mod<-read_rds("record_table_mod.rds")

days_between = as.numeric(diff(record_table_mod$Date_ymd))
daysfromstart <- cumsum(days_between)
daysfromstart <- c(0,daysfromstart) ### get data in terms of days from first record (time 0)

set.seed(11)
optMarathon<-mle(daysfromstart,"Exponential",40300) # end date picked number greater than longest time
optMarathon$par</pre>
```

#### Residuals

From the help: "Outputs the residuals (values of the compensator at the times of arrival) of a Hawkes process. Useful function for diagnosis through the random time change theorem: the residuals should follow a unit rate Poisson process" Based on the example in the help I assume should follow the y=x line... we see divergence here suggesting an issue (in what direction?)

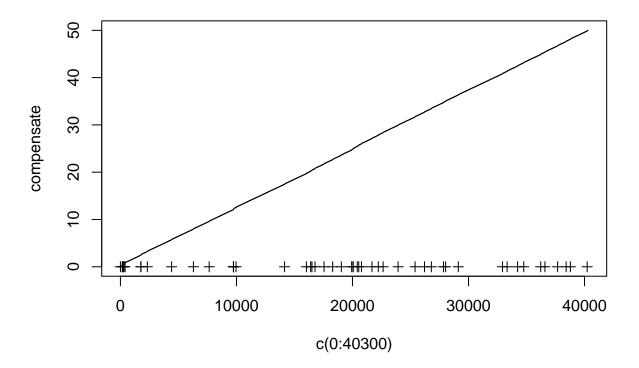

```
resid<-residuals(daysfromstart, fun = optMarathon$par[1], repr = optMarathon$par[2],
                  family = "exp", rate = optMarathon$par[3])
resid

#### Compensator

From the help: the compensator (integrated intensity) of a Hawkes process...kind of cool, can see how the events (world records) up the intensity. Event times are the plus symbols plotted below the intensity function line.

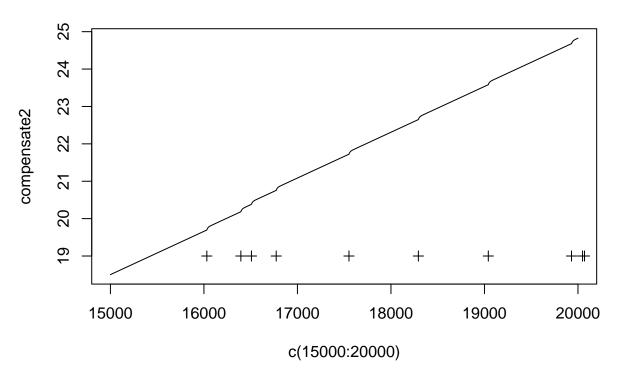

## **Full time period**

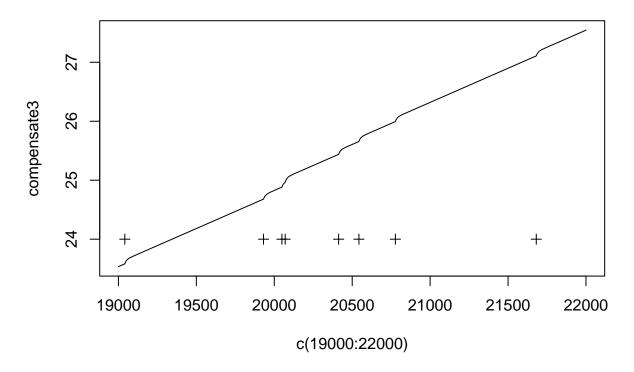

# First 4000 days

# Days 15,000 to 20,000

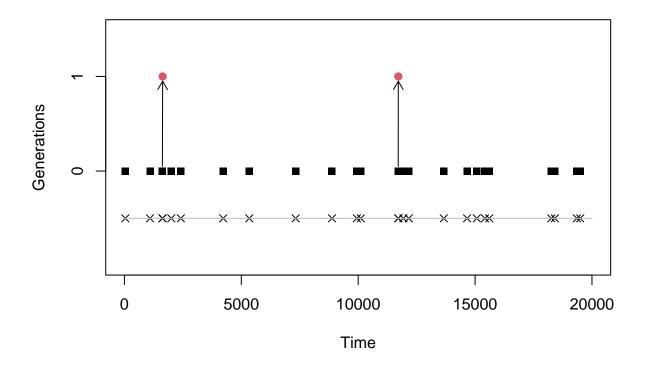

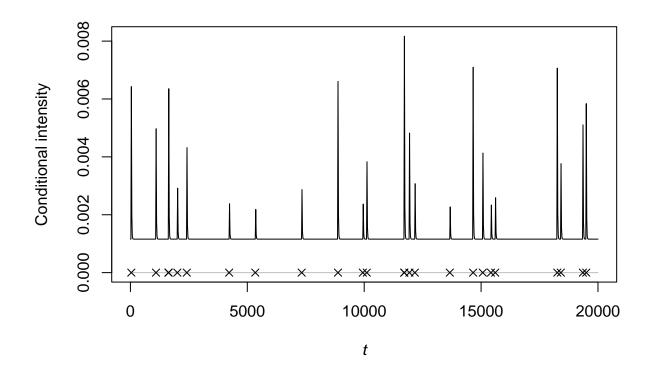

### Simulation using Hawkes model with MLE parameter estimates from data

Simulation for the same number of days used in the estimation. Last plot is the residuals - totally unclear to me what these are...I guess of the simulated data vs the exact values from the model? Generally seem to follow the y=x line but some runs don't.

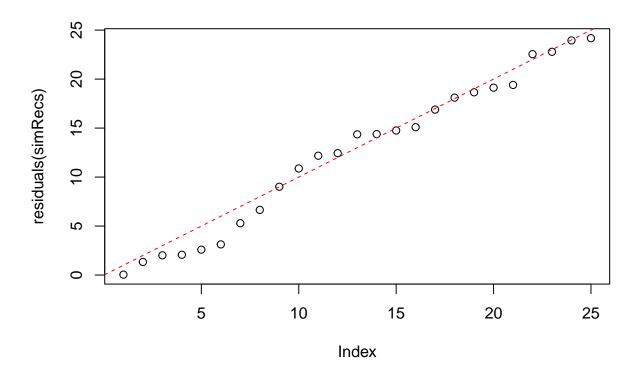

The second plot is the intensity - not easy to see, I think maybe a scale issue (not sure why it appears 0 with a few spikes, and to me those spikes don't correspond to plot one events).

plot(simRecs, intensity = TRUE)

```
plot(residuals(simRecs))
abline(0, 1, col="red", lty="dashed")
```

test
